# Including files

A block marked <include shows lines from another file, so this document can talk about include/greet.sh without a copy of it that goes stale. mdsh writes the lines into the block, so the file reads well anywhere markdown does. The path is relative to this file. Without from= or to=, the whole file is included:

include/greet.sh

```
#!/bin/sh
# greet.sh prints a greeting for each name it is given.

greet() {
    printf 'hello, %s\n' "$1"
}

for name in "$@"; do
    greet "$name"
done
```

An include block never runs and has no name, even when its language is sh. from= and to= pick lines, counted from 1 and inclusive. number_on asks for line numbers when the document is shown, so the excerpt still lines up with the source. Here is just the function:

include/greet.sh, lines 4–6

```
4  greet() {
5      printf 'hello, %s\n' "$1"
6  }
```

The fence's language is the language the lines are shown in:

include/greet.sh, from line 8

```
for name in "$@"; do
    greet "$name"
done
```

Includes sit alongside ordinary blocks. This one runs the script shown above:

sh {#run}

```
sh include/greet.sh world mdsh
```

```
hello, world
hello, mdsh
```

Run mdsh include.md to print this document with line numbers where they're asked for, or mdsh -w include.md to refresh the lines stored in each block.
